AUTHORS: Novikov, G. I., Polyachenok, O. G.

TITLE: Thermographic method of measuring the pressure of saturated vapors of difficultly volatile compounds

PERIODICAL: Zhurnal neorganicheskoy khimii, v. 6, no. 8, 1961, 1951-1952

TEXT: The authors used the "boiling point" method which has the advantages of the method by L. G. Berg (Ref. 2: IZV, Sektory fiz.-khim. analiza, 22, 140 (1953)). This method makes it possible to determine the moment when the vapor pressure of the substances equals the pressure outside the reaction vessel. In the present case, this moment was determined from the temperature drop of the substances, which occurred with their increasing evaporation near boiling point. The apparatus required is shown in Fig. 1. When experimenting with hygroscopic and easily oxidizable substances, the reaction vessel is connected to a vacuum apparatus and filled with pure and dry nitrogen. The current from the differential thermocouple is measured by a mirror galvanometer of 10^{-9} a/mm.m sensitivity. Gradual pressure drop was effected in the system at constant temperature, and the Card 1/3

S/078/61/006/008/010 '018
B127/B220

values of the manometer (p) and the galvanometer (1) were plotted in a diagram. On reaching the boiling point, the substance practically does not volatilize from the operating room, and the corresponding curve in the coordinate system is a straight line parallel to the p -axis. The diffusion current of the substance changes at the boiling point in proportion to the difference between saturated vapor pressure and gas pressure in the whole system, and corresponds to the second straight line which encloses an angle of about 100° with the first one. The point of intersection of the two straight lines corresponds to the saturated vapor pressure of the substance tested. There are 2 figures, 1 table, and 3 references: 1 Soviet-bloc and 2 non-Soviet-bloc. The reference to English-language publications reads as follows: Handbook of Chemistry and Physics, 37 ed. (1955-1956).

AUTHORS: Novikov, G. I., Andreyeva, N. V., Polyachenok, O. G.

TITLE: New method for the synthesis of low tungsten chlorides

PERIODICAL: Zhurnal neorganicheskoy khimii, v. 6, no. 9, 1961, 1990-1993

TEXT: The object for the present study was to elaborate a method permitting the production of larger quantities (kilograms) of low tungsten chlorides. Production by reduction of WCl_6 with hydrogen is not advantageous, and for

larger quantities it also requires special apparatus because of the danger of explosion hazard. This study gives theoretical considerations and their experimental confirmation with regard to the reduction of WCl_6 with

phosphorus. On the basis of the thermodynamic data (S. A. Shchukarev, G. I. Novikov et al., Referaty dokladov VIII Mendeleyevskogo s"yezda, (Abstracts of the reports from the 8th Mendeleyev Congress), no. 4, sektsiya fiz. khimii, M., 1958, p. 220), a good yield of the compounds WCl_5 and WCl_4

Card 1/4

New method for the synthesis...

26282
S/078/61/006/009/001/010
B107/B101

is found to form from WCl_6 and white phosphorus at 200°C . Moreover, the equilibrium of the reaction $[\text{WOCl}_4]_{\text{s}} + (\text{PCl}_3)_{\text{g}} = [\text{WCl}_4]_{\text{s}} + (\text{POCl}_3)_{\text{g}}$ at 200°C lies almost entirely on the right-hand side, so that the final reduction product would be free of contaminating oxychloride (s = solid; g = gas). Phosphorus has also the advantage that it may be accurately dosed and the reaction conducted in the evacuated glass vessel. Red phosphorus was used for the experiments and the reaction temperature was therefore raised to $250\text{--}300^\circ\text{C}$. WCl_6 was prepared by reaction of tungsten with chlorine at $500\text{--}600^\circ\text{C}$. A glass apparatus (Fig.) was used for preparing low chlorides. WCl_6 and phosphorus were filled into vessel B. For the preparation of WC_{15} , slightly more than the stoichiometrically required quantity of phosphorus was used, slightly less for that of WC_4 . The vessel is then evacuated and sealed at a. B is heated to $250\text{--}300^\circ\text{C}$, the volatile PCl_3 and POCl_3 are condensed in C. After the reaction, C is

Card 2/4

26282
S/078/61/006/009/001/010
B107/B101

cooled by liquid oxygen and sealed at c. B is further heated to 300-350°C. The volatile WCl_5 is thus driven out to A together with the residual PCl_3 , while the non-volatile WCl_4 remains in B. The apparatus is sealed at b, and the content of A is purified from residual phosphorus chloride by sublimation in vacuum. As shown by analyses, the WCl_5 thus produced contains a maximum of 0.09% phosphorus, WCl_4 a maximum of 0.17% phosphorus. Experiments showed that it is impossible to obtain pure WCl_2 by the same method. At best, the product only contains 1% phosphorus. Some non-volatile tungsten phosphides are supposed to form under these conditions. For the production of WCl_2 , at 400-450°C disproportionation of WCl_4 is therefore recommended: $3 \text{WCl}_4 = 2 \text{WCl}_5 + \text{WCl}_2$. There are 1 figure, 3 tables, and 9 references: 5 Soviet and 4 non-Soviet.

✓ Spectrographic determination of impurities in vanadium.
P. M. Polyakov and A. K. Rusanov. *Zavodskaya Lab.* 21,
1970, p. 1950; cf. *C.I.T. 60, 3810*.—The analysis of V_2O_5
was carried out with 3 types of C electrodes. (a) Al was
detd. by placing 20 mg. V_2O_5 in a hollow 3 mm. in diam., 6
mm. deep, and 1.5-mm. wall thickness, and arced against a
pointed cathode. The intensification and weakening of Al
and V lines (Al 3961.53 and V 3951.06 Å.) occurred simul-
taneously over a considerable interval of arcing. The
curve ΔS vs. $\log C$ covered a concn. range of 0.001-0.3%
Al with a probable error of $\pm 12\%$. (b) Powd. V_2O_5 mixed
with graphite contg. 4% NiO was placed in hollows of both
electrodes identical with the anode of a. The blackening
curves of Ni II 2437.80 and Ni I 2457.47 Å. in an a.-c. arc
and in a spark indicated an initial rise followed by a drop in
temp. The ΔS - $\log C$ curves were satisfactory for the detn.
of 0.001% Mn, Mg, and Cu and 0.01% Si and Fe with a
probable error of $\pm 9-12\%$. (c) V_2O_5 (40 mg.) mixed with
graphite (1:1) contg. 0.6% SnO₂ was placed into half of a
large hollow in the anode and arced against a pointed cath-
ode. The evapn. of Sb and Bi was complete in 80 sec. The
 ΔS - $\log C$ curve enabled the detn. of 0.001% Sb and Cd,
0.004% Pb and As, and 0.01% Bi and Zn with a probable
error of $\pm 11-12\%$. P was similarly detd. but without an
internal standard. It completely evapd. in 30-45 sec. I. Benenowitz

POSSIBILITY OF A TOXIC EFFECT OF HEAVY WATER
ON AGRICULTURAL PLANTS. Yu. A. Polyakov.

Pochvovedenie, No. 7, 25-32(1953) July.

In laboratory experiments with oats and barley it was found that heavy water and heavy hydrogen when contained in the nutrient medium, participated in the vital activity of the plants. D₂O had a negative effect on the growth and development of the plants, proportional to its concentration. This effect was most apparent when the concentration exceeded 30 to 40%. The mechanism causing this negative effect, although it has not been adequately investigated, may be explained by the great physical inertness of heavy water. The article is illustrated by charts and graphs.

TITLE	:	Study of Molds Most Frequently Encountered in Natural Curing of Tobacco	
ORIG. PUB.	:	Dohanyipar, 1958, okt., 21-28	

ABSTRACT : Among the molds the most widespread and detrimental in tobacco manufacture are: Mucor, Racemosus, Aspergillus, Glaucus, Aspergillus niger, Penicillium expansum and Penicillium glaucum. In addition to morphology, anatomy and optimal conditions of proliferation of the above-stated molds, results of experiments are presented which show that their spores are extremely widespread in the areas of tobacco manufacture. Climatic conditions of natural curing not only do not decrease, but on the contrary increase the viability of the spores.

TITLE: Time-wise asymptotic propagation of neutrons during pulsed neutron logging

SOURCE: Yadernaya geofizika. Vy*pusk 1963 g. Moscow, 1963, 80-117

TOPIC TAGS: geophysics, geophysical prospecting, neutron asymptotic propagation, pulsed neutron logging, neutron propagation

ABSTRACT: In order to disclose the most important relationships between the reading of a pulsed neutron logging equipment and the parameters of the investigated minerals, the diameter of the well, and the properties of the medium filling the well, a simplified approach is used, in which the pulse source is assumed to be a point emitting thermal neutrons. The differential equations of this boundary problem are solved by the integral transformation method

Card 1/2

ACCESSION NR: AT4001511

with successive application of the direct Laplace transform (with respect to the time), Fourier transform (with respect to the well axis), and Fourier-Bessel transform (with respect to the radial coordinate), and with subsequent inverse transformations. The cases of strong and weak absorption are considered separately. The mathematical results are interpreted physically and an approximate connection is obtained between the diagrams of pulsed neutron-neutron logging and the sought properties of the rocks, and also allow an estimate of the dependence of the relative differentiation of the different beds on the radius of the well, on the parameters of the rocks, on the time, and on other factors. The numerous conclusions resulting from the analysis of the solutions lead to the recommendations that in interpreting the well-measurement data it is necessary to establish first of all whether the absorption is weak or strong, and that weak absorption will be most frequently encountered for most applications of neutron-neutron logging, particularly in the logging of oil and gas wells. TITLE: Fusibility diagrams of systems formed by samarium and ytterbium di- and trichlorides with potassium chloride

SOURCE: Zhurnal neorg. khim., v. 9, no. 2, 1964, 472-475

TOPIC TAGS: samarium dichloride, samarium trichloride, ytterbium dichloride, ytterbium trichloride, potassium chloride, binary chloride fusibility, fusibility diagram

ABSTRACT: This work resulted from the lack of data on the stabilizing action of alkali halides on the dihalides of rare earths. The formation of solid phase compounds was observed and complexes were traced in the liquid and gaseous phases of trichlorides. Since there also is no literary data on the effect of KCl on rare earth dichlorides, fusibility tests of Sm and Yb di- and trichlorides with KCl were made and fusibility diagrams plotted. It was found that the solid state compound $KCl \cdot 2SmCl_2$ decomposes during melting, while $KCl \cdot YbCl_2$ melts without decomposition. There is a similarity of

Card 1/2

ACCESSION NR: AP4012450

these fusibility diagrams with those of $\text{SrCl}_2\text{-KCl}$ and $\text{CaCl}_2\text{-KCl}$ due to the similarity of ionic radii of Sr^{2+} - Sm^{2+} and Ca^{2+} - Yb^{2+} (1.27 and 1.06 Å). The $\text{SmCl}_3\text{-KCl}$ system showed, in addition to the $3\text{KCl}\cdot\text{SmCl}_3$ and $2\text{KCl}\cdot\text{SmCl}_3$ (already known), a new compound $\text{KCl}\cdot 2\text{SmCl}_3$, while the $\text{YbCl}_3\text{-KCl}$ system forms only $3\text{KCl}\cdot\text{YbCl}_3$. Complex ions were observed in the liquid state. It was also found that a marked influence of KCl on the relative stability of rare earth di- and trichlorides can only be expected for neodymium dichloride. Orig. art. has: 2 Figures.

TITLE: Possibility of macroscopic manifestations of violation of
microscopic causality

SOURCE: Zhurnal eksper. i teor. fiz., v. 46, no. 2, 1964, 755-763

TOPIC TAGS: relativity, gravitation, cosmology, microscopic causal-
ity condition, superluminal signal, special relativity, superluminal
sound, gravitational collapse, noncausal theory

ABSTRACT: The possible appearance of superluminal signals in the
kinematics of special relativity is discussed. Conditions which
the particle mass must satisfy in order for such signals to actually
arise are determined, and the propagation of superluminal sound,
which acquires a macroscopic character in strongly compressed matter,
is described by means of a time-like mass tensor. A field-theoreti-
cal model which leads to an unlimited increase in the ratio of the
pressure to the energy density and by the same token to an increase
in the ratio of the velocity of sound to the velocity of light is

Card 1/2

ACCESSION NR: AP4019245

considered. It is established that sufficiently strong violation of microscopic causality leads to an elimination of the gravitational collapse (to contraction of a body of large mass or of a world to a point). The paper contains an analysis of the principal feasibility of constructing a non-causal theory and of a few macroscopic effects due to non-causality. "The authors are deeply grateful to I. Ye. Tamm and V. L. Ginzburg for reviewing the manuscript and for valuable remarks, to A. D. Sakharov and Ye. L. Feynberg for a discussion of the work, to Ya. B. Zel'dovich for stimulating criticism, and to T. A. Eminadze for discussions which have led to the writing of this paper." Orig. art. has: 22 formulas.

AUTHOR: Polyachenok, O. G.; Novikov, G. I.TITLE: On the pressure of saturated vapor in the LaCl_3 -La, PrCl_3 -Pr, and NdCl_3 -Nd systems

SOURCE: Zhurnal neorganicheskoy khimii, v. 8, no. 7, 1963, 1785-1786

TOPIC TAGS: rare earths, rare earth chlorides, lanthanum, praseodymium, neodymium, PrCl_3 , NdCl_3 , LaCl_3 , vapor pressure, solubility, boiling-point method, heat of reaction, Pr(II), Nd(II)

ABSTRACT: The vapor pressure of the PrCl_3 -Pr, NdCl_3 -Nd, and LaCl_3 -La systems and the solubility of the rare earths in the chlorides of these systems were determined in the 1130—1350°C range. The vapor-pressure samples weighing 0.1—0.2 g were measured by the "boiling-point" method in heavy-walled quartz ampoules lined with molybdenum to prevent reaction of the rare earths with quartz. Vapor-pressure diagrams plotted (see Enclosure), indicate that

Card 1/5

ACCESSION NR: AP3003486

dissolution of atomic La occurs and that ions of Pr(II) and Nd(II) form in the melt. In all three systems the trichloride was the only compound to vaporize. Instability of the dichlorides in the vapor phase is probably associated with their high heat of vaporization. The positive deviation from Raoult's law observed in the PrCl_3 -Pr system may be attributed to the presence of some atomic Pr. The experimental heat of vaporization in the single-phase region was close to that of the pure chlorides (LaCl_3 , PrCl_3 , and NdCl_3), indicating that the overall heat effect of processes occurring during the dissolution of the trichlorides in the melt was close to zero. The difference between the heat of vaporization of the pure trichlorides and that of NdCl_3 and PrCl_3 in the phase-separation region is governed by the heat of reaction of the disproportionation of the dichlorides. The latter was found to be 38 ± 10 kcal for NdCl_2 at an average temperature of 1250°C , and 24 ± 10 kcal for PrCl_2 at an average temperature of 1230°C . For thermodynamic calculations from the data obtained on the disproportionation of the dichlorides, more precise information concerning the nature of ions formed in the melt on dissolution of the metals, as well as experimental data on

from hydrolytic lignin

SOURCE: AN SSSR. Doklady, v. 164, no. 3, 1965, 598-601

TOPIC TAGS: hydrolysis, plant growth, organic nitro compound, molecular weight,
quinone, chemical reactor, polysaccharide, solvent extraction, chemical precipitation,
polycarboxylic acid, biochemistry, oxidation

ABSTRACT: The authors have developed and applied a method of fractional, gradual
oxidation and hydrolysis of condensed lignin with nitric acid in an aqueous medium
at 100°. The gradual introduction of the oxidant in the reaction mixture leads
to a minimum breakdown in the quinonic acids formed and permits the process to be
carried out for a small consumption of oxidant. As the object of the investi-
gation, different kinds of technical lignins subjected to prolonged condensation
treatment were used. Lignin (lignin content, according to König, was 85 - 90%,
 OCH_3 -- 4.7 - 5%) in the amount of 500 grams in 5 liters of water -- was placed
into a stainless steel reactor fitted with cooling coils, a reflux condenser, a
mixer, and an electric heating attachment. The suspension of lignin in water
was heated to 100°. After the mixer had stirred the mixture gradually

Card 1/2

0915 1718

ACC NR: AP6024160

for six hours, nitric acid (1.35) was added in the amount of 0.75 kg (based on the calculation for the monohydrate), with a gradual supply of heated air into the lower part of the reactor. The reaction proceeded vigorously with the evolution of gaseous products and in some cases required cooling. At the completion of the reaction, the solution containing only traces of nitric acid was filtered free of the insoluble residue and was neutralized with calcium carbonate to pH 2.8 - 3. In order to isolate the quinonic acids, the solution was further extracted with methylethylketone. The extract was dried with sodium sulfate. After separation of a larger part of the solvent in vacuum, a thick syrup was poured into dry petroleum ether. The precipitating dark-red oil was separated from the other, dried in a vacuum drier at 40° and in a vacuum dessicator over alkali, and then over phosphoric anhydride for a period of a week. The yield was up to 30% of the lignin weight used. The resulting brick-red, very hygroscopic powder dissolved readily in water and in polar organic solvents.

In investigating its properties, the fraction dissolved when heated in dioxane was used. The product was titrated potentiometrically in an aqueous solution as a strong acid. Its molecular weight (cryoscopically determined) in dioxane was 286. The gram-equivalent was 132. The content of carboxylic groups in the molecule is approximately two. Elemental composition (in %) was as follows: C -- 45.1, H -- 3.74, O -- 45.84, and N -- 5.32.

Upon comparison of experimental and calculated data (elemental composition, molecular weight, gram-equivalent, and infrared spectra), it is assumed that the products obtained by the authors can be classed as quinonic nitropolycarboxylic acids. This paper was presented by Academician A. L. Kursanov on 23 November 1964.

TITLE: Oxidation of organic substances through a palladium membrane

SOURCE: Elektrokhimiya, v. 1, no. 8, 1965, 968-974

TOPIC TAGS: formic acid, formaldehyde, oxidation, electrochemistry, palladium

ABSTRACT: The diffusion of hydrogen (produced during chemisorption of formic acid and formaldehyde) through a palladium membrane was studied. It was found that the activity of the palladium membrane depends to a significant extent on its pretreatment. In this work the membrane was heated in an oxidizing bunsen burner flame, washed with 1:1 HCl and twice with distilled water. After pretreatment the membrane was tightly mounted between the ground surfaces of two different cells. When the cells on both sides of the membrane contained the same solution, the potential difference did not exceed 10 mv. Formic acid or formaldehyde was introduced into one of the cells and the potential shift was recorded on both sides of the membrane on two S1-19 oscilloscopes. It is believed that the membrane potentials on both sides

are controlled by the equilibrium between the adsorbed hydrogen and hydrogen ions in the solution:

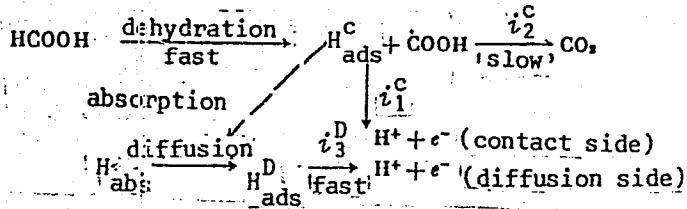

Electrooxidation of formic acid and formaldehyde through a palladium membrane was studied. On the diffusion side the membrane was anodically polarized by an electronic potentiostat, usually at $\phi_r = 0.6$ v. When there was no organic substance on the contact side of the membrane a weak cathode current was observed in the diffusion side of the cell. When the organic substance was introduced into the solution on the contact side of the cell an anode current began to flow through the diffusion side of the cell. When this solution was replaced again by 7N KOH or 1N H_2SO_4 without the organic substance, the diffusion current dropped to zero. This behavior was reproducible upon numerous trials (see fig. 1 of the Enclosure). The anode current in the diffusion part of the cell which occurs in the presence of organic substance in the contact part of the apparatus results only due to ionization of hydrogen which diffuses through the palladium membrane. It is shown that the occurrence of hydrogen on the diffusion side of the membrane is explained only by the dehydrogenation of formic acid during chemisorption on the membrane. It is shown that the oxidation current through the membrane is determined by the rate of formation of the

adsorbed hydrogen and competition of relatively fast ionization processes of the adsorbed hydrogen on the contact side, absorption by palladium and diffusion to the other side. The following general scheme is proposed:

"The authors express their gratitude to A. N. Frumkin for valuable discussion and I. A. Bagotskaya for consultation and help in the organization of this work." Orig. art. has: 6 figures.

AUTHOR: Polyak, A.I.

TITLE: Changes in the immunological reactivity and morphological structure of lymphoid tissue at different stages of radiation injury

PERIODICAL: Meditsinskaya radiologiya, v. 10, no. 19, 1962, 51-54

TEXT: The way in which ionizing radiation suppresses the immunogenesis is still the object of discussion. The author tried to follow up the immunological reactivity of lymphoid tissue at various stages of radiation injury in the irradiated animal itself as well as after transplantation of irradiated lymphoid tissue into a healthy, nonirradiated animal, a method employed for the first time. Rabbits were exposed to the x-rays in a dose of 500 r, and were immunized by a single injection, of a suspension containing 2000 million organisms from a 1 day old Escherichia coli culture, into the hind leg. Tissue from a popliteal lymph node was then investigated histologically and serologically and was partly transplanted into the anterior eye chamber of a healthy rabbit where the changes could be observed with-

out interference by the toxic products circulating in the irradiated rabbit. In the first group, immunized 3 days before the irradiation, marked degenerative changes occurred: loss of follicular structure, granulation round the plasma cells, and numerous Russel bodies could be seen. Numerous transition forms and mature plasma cells represented evidence for a normal immunological response. The antibody titre increased 36 times above control values. In the second group, immunized 10 days after the irradiation the degenerative changes were at their peak, immature and mature plasma cells were still present, but the most radiosensitive elements, the cells of the cambial layer, which are alone capable of forming new plasma cells, had disappeared. The antibody titre had increased only 3 times above control level. In the 3rd group, immunized 1 month after the irradiation, a great number of cambial cells could be seen, but the time had apparently been insufficient to permit their maturation into plasma cells, producing antibodies as the titre had increased only 10 times above control level. There is 1 figure.
